# 1 Animals and Environments

## Introduction

- ▷ What is physiology?
  - Form and function of organisms; the study of how organisms work.
- ▷ Central questions of physiology: **mechanism** and **origin**.
  - Mechanism:
    - Refers to the **components** of living organisms and understanding **how** components interact to enable the organism to function.
  - Origin:
    - Asks why a mechanism exists, or **what** is the mechanistic **adaptive significance** of the mechanism.
  - Mechanism and adaptive significance are distinct concepts; knowing about one doesn't necessarily mean you know anything about the other.
- ▷ Krogh's principle:
  - "For such a large number of problems there will be some animal of choice or a few such animals on which it can be most conveniently studied."
  - This idea is central to disciplines that rely on the *comparative method*. The key take away: there is unity in diversity; many organisms are very much alike at the most fundamental levels.
- ▷ Physiology subdisciplines:
  - Mechanistic: emphasizes the mechanisms by which organisms perform their life functions.
  - Evolutionary: emphasizes evolutionary origins and the adaptive significance of traits.
  - Comparative: emphasizes the way in which diverse phylogenetic groups resemble and differ from each other.
  - Environmental: emphasizes the ways in which physiology and ecology interact.
  - Integrative: emphasizes the importance of all levels of organization, from genes to proteins and tissues to organs in order to better understand whole physiological systems.

## Homeostasis

- ▷ Important ideas to remember:
  - Organisms are structurally dynamic; form stays relatively static while individual cells recycle frequently.
  - Most cells are exposed to the **internal** environment, not external.
  - Internal cells may vary or kept constant with the environment.
- ▷ Temperature regulation:
  - **Conformity**: organism's internal temperature **correlates** with external temperature in a particular range of temperatures.
  - **Regulation**: internal environment is held mostly **constant** using cellular mechanisms.
- ▷ **Homeostasis**: the coordinated physiological processes that maintain a relatively constant state in the organism.
  - **Positive feedback**: less common in homeostasis due difficulty in regulation; leads to runaway effect easily.
  - **Negative feedback**: more common in homeostasis due to self correcting nature.
  - **Effector**: executes the change in action that produces an effect, e.g. signals to increase temperature.
  - **Sensor**: sense changes in environment and sends information to the effector.

## Physiology and Time

- ▷ Timeframes of physiological change:
  - **Acute**: short-term, reversible, and quick to adapt to changes in environment. Usually minutes to hours.
  - **Chronic**: long-term after prolonged exposure to new environments. Changes are usually reversible, but often slower.
    - Chronic can be termed acclimation, or phenotypic plasticity/flexibility.
    - Repetitive acute responses usually lead to chronic responses.
  - **Evolutionary**: changes due to alteration in gene frequencies in **populations** exposed to new environments.
- ▷ Acclimation is **not the same** as adaption.

- *Adaption* is an evolutionary trait present at high frequency in a population due to survival/reproductive advantages.
- Not all traits are adaptations.
- The amount of natural variation in a trait must be considered across populations, species etc.

## 2 Molecules and Cells in Animal Physiology

### Cell Membrane Review

- ▷ Major cell membrane structures:
  - **Glycoproteins**: carbohydrate chain attached to a protein.
  - **Glycolipids**: similar to glycoproteins, but attached to lipid molecules.
  - *Glycocalyx*: combination of glycoproteins and glycolipids on the surface of cell.
  - **Integral proteins**: embedded in phospholipid bilayer.
  - **Peripheral proteins**: associated with one side of the bilayer.
- ▷ **Unsaturated phospholipid**: when hydrocarbon tails contain double bonds (less hydrogen).
  - Increase membrane fluidity due to extra space created.
- ▷ The fluidity of the cell membrane allows proteins to form complexes and dynamically change shape.

### Enzyme Fundamentals

- ▷ **Enzymes**: a protein catalyst that plays two primary roles: **accelerating** and **regulating** chemical reactions.
- ▷ *Substrates*: the initial reactants of the reaction that an enzyme catalyzes.
- ▷ **Enzyme-substrate-complex (E-S)**: a combination of enzyme (E) with a molecule of substrate (S) that starts a reaction.
  - Usually stabilized by **non-covalent** bonds.
  - The substrate is converted to a product by first becoming an *enzyme-product complex (E-P)*, then dissociates to yield free product and free enzyme.
  - $E + S \rightleftharpoons E-S \rightleftharpoons E-P \rightleftharpoons E + P$
- ▷ **Saturation kinetics**:
  - **V<sub>max</sub>**: the maximum velocity of a reaction and is determined by:
    - the **number** of active enzyme molecules present relative to substrate.
    - the catalytic **effectiveness** of each enzyme molecule.
    - These properties usually undergo heavy selection pressure.

- *Saturated*: all enzymes are occupied by a substrate molecule nearly all the time and now unable to increase reaction velocity.
- **Hyperbolic**: asymptotically approaches  $V_{\max}$ 
  - Tends to happen when enzymes have just one substrate binding site.
  - Or when substrate sites behave independently
- **Sigmoidal**: approaches  $V_{\max}$  with a sigmoidal trajectory.
  - When multiple sites influence each other.
- **Turnover number ( $k_{\text{cat}}$ )**: the **total effectiveness**, expressed as the number of substrate molecules converted to product per second by each enzyme molecule when saturated.
  - Depends partly on the *activation energy* of the enzyme-catalyzed reaction.
  - **Activation energy**: the energy required for the substrate to enter the *transition state*.
  - **Transition state**: the intermediate chemical state between substrate and product.
  - Enzymes **lower the activation energy** required to enter transition state.
- ▷ **Enzyme-substrate affinity**:
  - The proclivity of the enzyme to form a complex with the substrate when they meet.
    - **Likely** complex formation results in **high-affinity**.
    - **Unlikely** complex formation results in **low-affinity**.
  - Affinity affects the shape of the reaction velocity.
    - **Higher** affinity produces a **steeper** velocity, and **lower** produces a more **linear** result.
  - **Half-saturation constant,  $K_m$** : the substrate concentration required to attain one-half maximum reaction velocity.
    - $K_m$  and enzyme-substrate affinity are **inversely related**.
    - i.e. **low-affinity** enzyme has a **greater  $K_m$** .
